## Pushdown Automata

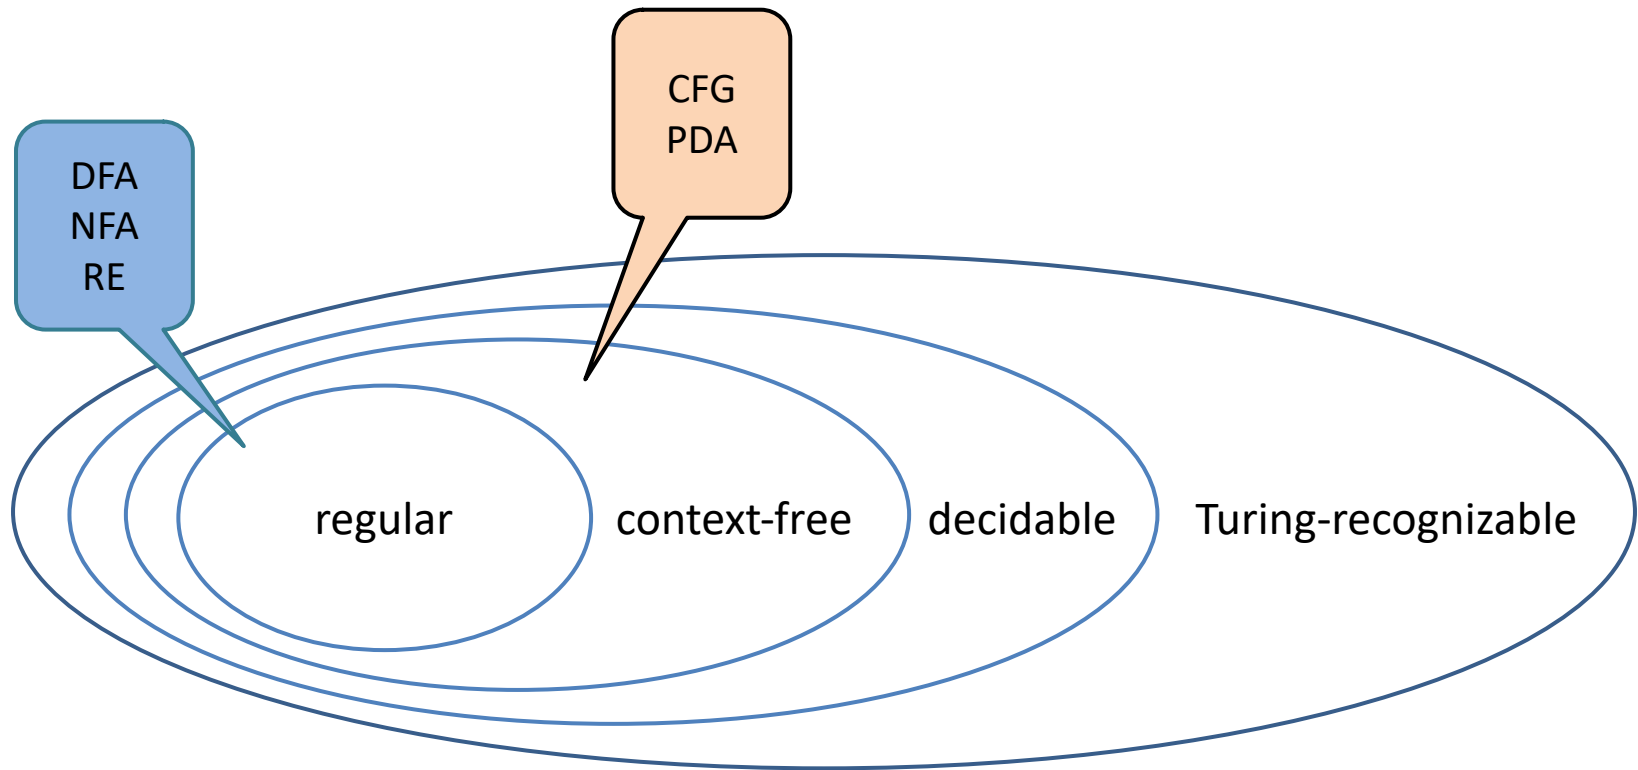

**Kun Suo**

Computer Science, Kennesaw State University

<https://kevinsuo.github.io/>

# Pushdown Automata (PDA)

---

# Pushdown Automata (PDA)

---

- Pushdown automatas are equivalent in power to context-free grammars (PDA=CFG)
- PDA can recognize some nonregular languages

# What does PDA look like?

---

finite automaton

Memory = 1

pushdown automaton

Memory = N

# What does PDA looks like?

---

pushdown automaton

- Pushdown automata has more memories than finite automata
- PDA = finite automata + **A stack (unlimited size)**

# Stack operation

---

- Push: add to the top of stack

# Stack operation

---

- Pop: remove from the top of stack

# To test whether 00111 is in $0^n1^n$

---

Single direction,  
read only input tape

$\{ 0^n1^n \mid n \geq 0 \}$

Single direction  
read only head

Stack

# To test whether 00111 is in $0^n1^n$

Stack

# Informal description for PDA to recognize some languages

- $A = \{0^n 1^n \mid n \geq 0\}$
- Read symbols from input
  - Operation
    - ▶ For every 0s, push 0 into stack
    - ▶ When read 1s, pop one 0 from stack for every 1
  - Determine accept/reject:
    - ▶ When finish reading string and there is no 0s in stack, **accept**;
    - ▶ When there exist 0s after 1s, **reject**.
    - ▶ When tape is not finished while the stack is empty, **reject**;
    - ▶ When tape finished while the stack is non-empty, **reject**;

# Informal description for PDA to recognize some languages

- $L = \{w \mid w \text{ has some features}\}$
- Read symbols from input
  - **STEP1:** If the language is regular, do not need to use stack; if not regul define operations on stack
  - **STEP2:** define operations:
    - ▶ When to push
    - ▶ When to pop
  - **STEP 3:** determine accept/reject:
    - ▶ Under which cases, accept
    - ▶ Under which cases, reject

# Question: Informal description

- $L1 = \{w \mid w \text{ has at least three } 1s\}$ 
  - This set is regular, so the PDA doesn't even need to use its stack.
  - The PDA scans the string and uses its finite control to maintain a counter which counts up to 3. The PDA accepts the moment it sees three ones.

# Question: Informal description

- $L_2 = \{w \mid w \text{ starts and ends with the same symbol}\}$ 
  - This set is regular, so the PDA doesn't even need to use its stack.
  - The PDA scans the string and keep track of the first and last symbol in its finite control. If they are the same, accepts.

# Question: Informal description

- $L_3 = \{w \mid w \text{ has more 1s than 0s}\}$       Single read-only input tape

- This set is not regular.

- The PDA scans across the input.

- ▶ POP: If it sees a 1 and its top stack symbol is a 0, it pops the stack. Similarly, if it scans a 0 and its top stack symbol is a 1, it pops the stack.
- ▶ PUSH: In all other cases, it pushes the input symbol onto the stack.

- After it scans the input, if there is a 1 on top of the stack, it accepts. Otherwise it rejects.

## Question: Informal description

- $L_4 = \emptyset$ 
  - Just reject.

# Definition of PDA (non-deterministic)

---

- PDA  $M=(Q,\Sigma,\Gamma,\delta,q_0,F)$ , where
  - 1)  $Q$ : set of states
  - 2)  $\Sigma$ : input alphabet,  $\Sigma_\epsilon=\Sigma\cup\{\epsilon\}$
  - 3)  $\Gamma$ : stack alphabet,  $\Gamma_\epsilon=\Gamma\cup\{\epsilon\}$
  - 4)  $\delta: Q\times\Sigma_\epsilon\times\Gamma_\epsilon\rightarrow P(Q\times\Gamma_\epsilon)$ ,  
transition function
  - 5)  $q_0\in Q$ : start state
  - 6)  $F\subseteq Q$ : accept state set

# PDA vs. NFA

---

A *pushdown automaton* is a 6-tuple  $(Q, \Sigma, \underline{\Gamma}, \delta, q_0, F)$ , where  $Q$ ,  $\Sigma$ ,  $\Gamma$ , and  $F$  are all finite sets, and

1.  $Q$  is the set of states,
2.  $\Sigma$  is the input alphabet,
3.  $\Gamma$  is the stack alphabet,
4.  $\delta: \underline{Q \times \Sigma_\epsilon \times \Gamma_\epsilon} \longrightarrow \mathcal{P}(Q \times \Gamma_\epsilon)$  is the transition function,
5.  $q_0 \in Q$  is the start state, and
6.  $F \subseteq Q$  is the set of accept states.

A *nondeterministic finite automaton* is a 5-tuple  $(Q, \Sigma, \delta, q_0, F)$ , where

1.  $Q$  is a finite set of states,
2.  $\Sigma$  is a finite alphabet,
3.  $\delta: Q \times \Sigma_\epsilon \longrightarrow \mathcal{P}(Q)$  is the transition function,
4.  $q_0 \in Q$  is the start state, and
5.  $F \subseteq Q$  is the set of accept states.

# Computation on PDA

- $M = (Q, \Sigma, \Gamma, \delta, q_0, F);$

input  $w = w_1 w_2 \dots w_m,$

$w_i \in \Sigma_\epsilon$

- Computation: (state, stack)

$(r_0, s_0), (r_1, s_1), \dots, (r_m, s_m),$

Where  $r_i \in Q, s_i \in \Gamma^*,$  satisfying

1)  $(r_0, s_0) = (q_0, \epsilon);$

At first, the first state is  $q_0$  and stack is empty

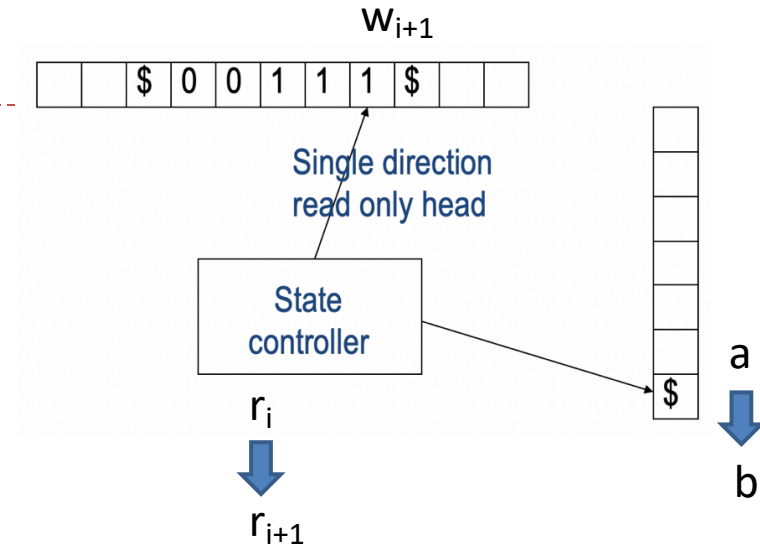

2)  $(r_{i+1}, b) \in \delta(r_i, w_{i+1}, a);$

where  $s_i = at; s_{i+1} = bt,$

$a, b \in \Sigma_\epsilon,$

$t \in \Gamma^*$  (t are other elements in stack)

After input  $w_{i+1}$ , state changes from  $r_i$  to  $r_{i+1}$  and the top element in stack changes from  $a$  to  $b$

# Computation on PDA

---

- Accept of computation:

3)  $r_m \in F$ ;

- M accepts w:

M is at accept states after input of w

- The language that M accepts:

$$L(M) = \{ x \mid M \text{ accepts } x \}$$

# PDA example

\$	000...0	111...1	\$
$q_1$	$q_2$	$q_3$	$q_4$

- $L = \{0^n 1^n \mid n \geq 0\}$
- $M_1 = (\{q_1, q_2, q_3, q_4\}, \{0, 1\}, \{0, \$\}, \delta, q_1, \{q_1, q_4\})$

We only put 0 or \$ into stack

$a, b \rightarrow c$   
 $a$ : input  
 $b \rightarrow c$ : the top of stack changes

$M_1$

# PDA example

\$	000...0	111...1	\$
